

# What are we weighting for?

A mechanistic model for probability weighting

Ole Peters   Alexander Adamou   Yonatan Berman   Mark Kirstein

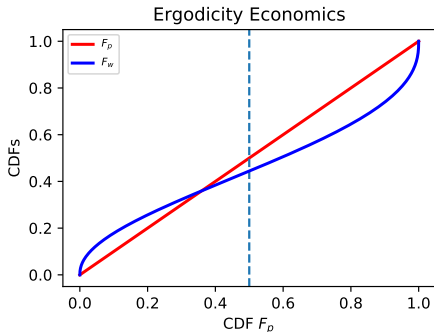

D-TEA 2020, 16 June 2020

UNIVERSITÄT LEIPZIG

Mathematisches Institut

- 1 inverse-S shape can be explained by difference in uncertainty
- 2 cautious estimation of probabilities generates such differences

Question

Estimation

Conclusion

# Definition of Probability Weighting (PW)

- low probabilities treated as higher; high probabilities treated as lower
- stable empirical pattern: inverse-S shape

Received wisdom:

- PW = maladaptive irrational cognitive bias

In search of a mechanism

- ↪ How does this pattern emerge?
- ↪ Can we derive a functional form (rather than fit a function)?

(Tversky and Kahneman 1992, p. 310, Fig. 1, relabelled axes)

Task: model payout,  $x$ , of a gamble as a random variable.

### Disinterested Observer (DO)

DO assigns  
probabilities  $p(x)$   
CDF  $F_p(x)$

### Decision Maker (DM)

DM assigns different  
probabilities  $w(x)$  (decision weights)  
CDF  $F_w(x)$

Numerically easy for any pair of distributions (models):

- 1 list values of DO's CDF,  $F_p(x)$ , at set  $x_i$
- 2 list values of DM's CDF,  $F_w(x)$ , at same  $x_i$
- 3 plot  $F_w(x)$  vs.  $F_p(x)$

Estimation

Conclusion

# Asymmetry from different locations

Mark Kirstein

## Interim conclusion

- DM's greater scale gives inverse-S shape (unimodal distributions)
- difference in locations gives asymmetry
- reproduces observations of probability weighting

# Experiencing probabilities

Main Result

Probability  
Weighting

Ergodicity  
Question

Estimation

Conclusion

- probabilities are not observable
- probabilities encountered as
  - known frequency in ensemble of experiments (DO)
  - frequencies estimated over time (DM)

↪ **estimates have uncertainties – cautious DM accounts for these**

# Estimating probabilities

## Rare Event

- $p(x) = 0.001$
  - 100 observations
  - $\sim 99.5\%$  of such time series will contain 0 or 1 events
  - Naïve estimation:  $\hat{p}(x) = 0$  or  $\hat{p}(x) = 0.01$
- ↪ either impossible or ten times (over)estimation

## Common Event

- $p(x) = 0.5$
  - 100 observations
  - $\sim 99.5\%$  of time series would contain between 35 and 65 events,
  - Naïve estimation:  $0.35 < \hat{p}(x) < 0.65$
- ↪  $< 50\%$  error in  $\hat{p}(x)$

↪ small  $p(x)$ , small count  
↪ small count, big uncertainty

# Relative estimation error is large for rare events

| Asymptotic probability | Most likely count | Standard error in count | Standard error in probability | Relative error in probability |
|------------------------|-------------------|-------------------------|-------------------------------|-------------------------------|
| 0.1                    | 1000              | 32                      | 0.003                         | 3%                            |
| 0.01                   | 100               | 10                      | 0.001                         | 10%                           |
| 0.001                  | 10                | 3                       | 0.0003                        | 30%                           |
| 0.0001                 | 1                 | 1                       | 0.0001                        | 100%                          |

**Table:**  $T = 10\,000$ , assuming Poisson statistics, relative estimation errors  $\sim 1/\sqrt{\text{count}}$

$\hookrightarrow$  small  $p(x)$ , small count  
 $\hookrightarrow$  small count, big uncertainty

To avoid surprises, let's say DMs **add estimation uncertainty**  $\varepsilon [p(x)]$  to every estimated probability, then normalize, s.t.

$$w(x) = \frac{p(x) + \varepsilon [p(x)]}{\int (p(s) + \varepsilon [p(s)]) ds}$$

This allows us to derive a functional form, e.g. for the Gaussian case

$$w(p) = p^{\frac{1}{\alpha^2}} \frac{(2\pi\sigma^2)^{\frac{1-\alpha^2}{2\alpha^2}}}{\alpha},$$

where DM's greater scale is  $(\alpha\sigma)^2$

Question

Estimation

Conclusion

Mark Kirstein

## Ergodicity Economics and probability weighting

- inverse-S shape appears as neutral indicator of a difference in opinion
  - reported observations consistent with DM's extra uncertainty
  - may arise from DM estimating probabilities over time
- ↪ Probability weighting is rational cautious behaviour under uncertainty over time
-

# Probability Weighting as an Estimation Issue

“It is important to distinguish [overweighting](#), which refers to a property of decision weights, from the [overestimation](#) that is commonly found in the assessment of the probability of rare events. [...] In many real-life situations, overestimation and overweighting may both operate to increase the impact of rare events.” (Kahneman and Tversky [1979](#), p. 281)

↪ distinguish between

- uncertainty estimation and
- “weighting”

we analyse the former and find very good agreement with the empirical inverse-S pattern

↪ How big is the residual “probability weighting” after accounting for uncertainty estimation?

Mark Kirstein

# Estimation Error Explains 99% of Probability Weighting

Tversky & Kahneman (1992)

Tversky & Fox (1995)

- similar fits of Gaussian &  $t$ -distributed model

→ How big is the residual “probability weighting” after accounting for estimation errors?

Tversky and Kahneman (1992,  $\gamma = 0.68$ )

$$\tilde{F}_w^{TK}(F_p; \gamma) = (F_p)^\gamma \frac{1}{\left[(F_p)^\gamma + (1 - F_p)^\gamma\right]^{1/\gamma}} \quad (1)$$

Lattimore, Baker, and Witte (1992)

$$\tilde{F}_w^L(F_p; \delta, \gamma) = \frac{\delta F_p^\gamma}{\delta F_p^\gamma + (1 - F_p)^\gamma} \quad (2)$$

We derive decision weight as a function of probability with  $(\alpha\sigma)^2$  as the DM's scale

$$w(p) = p^{\frac{1}{\alpha^2}} \frac{(2\pi\sigma^2)^{\frac{1-\alpha^2}{2\alpha^2}}}{\alpha}, \quad (3)$$

which is a power law in  $p$  with a pre-factor to ensure normalisation
